

0.1 The Complex Lattice

Theorem 1 *Let ω_1, ω_2 be linearly independent points in \mathbb{C} . Then define the lattice*

$$L = Z\omega_1 + Z\omega_2$$

Then there exists an elliptic curve that is isomorphic to \mathbb{C}/L .

Define $G_k(L) = \sum_{\omega \in L} \omega^{-k}$. Then define the Weierstrass $\wp(z)$ function as follows:

$$\wp(z) = \frac{1}{z^2} + \sum_{\omega \in L} \left(\frac{1}{(z - \omega)^2} - \frac{1}{\omega^2} \right) \quad (1)$$

Then this function can easily be shown, by applications of complex analysis, to be convergent and meromorphic, as well as periodic. Then the derivative $\wp'(z)$ is

$$\wp'(z) = -2 \sum_{\omega \in L} \frac{1}{(z - \omega)^2} \quad (2)$$

Now we have a isomorphism from the additive group on \mathbb{C}/L to the the group of elliptic points on $E(\mathbb{C})$, by the map

$$z \rightarrow (\wp(z), \wp'(z)), \quad 0 \rightarrow O$$

with E being defined as

$$E : y^2 = 4x^3 - g_2x - g_3 \quad (3)$$

where $g_2 = 60G_4, g_3 = 140G_6$ Note that the periodicity will give:

$$(\wp(z_1), \wp'(z_1)) \oplus (\wp(z_2), \wp'(z_2)) = (\wp(z_1 + z_2), \wp'(z_1 + z_2)) \quad (4)$$

which gives rise to the corresponding group law on elliptic curves.

Now we relate the j -invariant on curves to the j -function of a complex lattice. First, let rescale our lattice L to $Z\tau + Z$ where $\tau = \frac{\omega_1}{\omega_2}$. Then the j -invariant related to the lattice parameter is

$$j(\tau) = 1728 \frac{g_2^3}{g_2^3 - 27g_3^2} \quad (5)$$

The proof of all of this we won't go into detail in this paper, but this gives rise to the relationship between the complex lattice and isogenies, mainly integer endomorphisms $[m]$ give rise to $z \rightarrow mz$, and for multiplication by a complex number β , we have $z \rightarrow \beta z$, which is defined when $\beta L \subseteq L$. A key theorem in [1] is that

$$\text{End}(E) \cong \{\beta \in \mathbb{C} | \beta L \subseteq L\} \quad (6)$$

For curves defined on a field K , there is a homomorphism $K \rightarrow \mathbb{C}$ if we linearly map the finite basis elements of K , $\alpha_1, \dots, \alpha_n$ respectively to any algebraically independent set of elements in \mathbb{C} , τ_1, \dots, τ_n , so we can regard $E(K)$ as a curve in \mathbb{C} .

0.1.1 Using Quadratic Lattices

Consider the case when our lattice $L = O_D$ where $D = \mathbb{Q}(\sqrt{-d})$ for some $d > 0$, where the basis elements will be $[1, \frac{1+\sqrt{-d}}{2}]$ or $[1, \sqrt{-d}]$ depending on whether d is $\{3\}, \{1, 2\} \pmod{4}$ respectively, which are quadratic integer fields.

Then define the Hilbert Class polynomial $H_D \in \mathbb{Z}[X]$ that is the minimal polynomial that contains the $j(L)$ as a root. There are many ways to calculate this, but we won't get to that in this paper. Thus, we can define an elliptic curve based on a square free discriminant D .
